A SPIRAL NEBULA AS A STELLAR SYSTEM,
MESSIER 31

BY EDWIN HUBBLE

ABSTRACT

Material.—The present discussion of M 31 is based on the study of about 350 photographs taken with the 60- and 100-inch reflectors, distributed over an interval of about eighteen years. Two-thirds of the total number were obtained by the writer during the five years 1923–1928. Since the image of the nebula is much larger than the usable fields of the telescopes, attention was concentrated on four regions centered on (1) the nucleus, (2) 23' north following, (3) 17' south, (4) 48' south preceding the nucleus. The combined area, with allowance for overlapping, represents about 40 per cent of the entire nebula.

Resolution.—The outer regions of the spiral arms are partially resolved into swarms of faint stars, while the nuclear region shows no indications of resolution under any conditions with the 100-inch reflector. Intermediate regions show isolated patches where resolution is pronounced or suggested.

Variables.—Fifty variables have been found, nearly all in the outer regions where resolution is pronounced. The survey is believed to be fairly exhaustive in the four selected regions down to 19.0 photographic magnitude.

Cepheids.—Forty of the variables are known to be Cepheids with periods from 48 days to 10 days and maxima from 18.1 to 19.3 photographic magnitude; one exceptional star varies from 17.9 to 19.2 in a period of 175 days. The period-luminosity relation is conspicuous, and the slope is approximately that found among Cepheids in other extra-galactic systems.

Distance of M 31 derived from Cepheid criteria.—Comparisons of period-luminosity diagrams indicate that M 31 is about 0.1 mag. or 5 per cent more distant than M 33, and about 8.5 times more distant than the Small Magellanic Cloud. Using Shapley’s value for the Cloud, we find the distance of M 31 to be 275,000 parsecs.
Distance measurements from Cepheid variables (Standard Candles)

• Hubble (1929): “A *Spiral Nebula as a Stellar System, Messier 31*”
• He discovered a **Cepheid variable** inside of the Andromeda (M31-V1).
• He used **Leavitt** (1908)’s **Luminosity-Period relation** to calculate the distance to M31. This distance was much greater than the size of the Milky Way per Shapley.
Spectroscopy: radial velocity measurements to trace the flow

- Use galaxies as “massless” particles to trace the flow caused by gravity or other things; this is similar to measuring the peculiar velocities of solar neighborhood stars in the Milky Way.
Spectroscopy: radial velocity measurements to trace the flow

- Instead of finding similar numbers of **blueshifted** and **redshifted** galaxies, Hubble found that most of the galaxies are **redshifted** — i.e., they appear to be moving away from us.

\[
\text{redshift } z = \frac{\lambda_{\text{observed}} - \lambda_{\text{rest}}}{\lambda_{\text{rest}}}
\]
Redshift and recession velocity at $z \ll 1$

- In 1920s, two technological advancements enabled the discovery of Hubble’s law
- Distance $D$ from standard candles like Cepheids ($L-P$ relation, aka Leavitt’s Law)
- Redshift $z$ from moderate resolution spectroscopy:
  $$z = \frac{\lambda_{\text{observed}} - \lambda_{\text{rest}}}{\lambda_{\text{rest}}}$$
- Inspecting the definition of $z$, does it look similar to the Doppler shift equation?
  $$\frac{v_r}{c} = \frac{\lambda_{\text{observed}} - \lambda_{\text{rest}}}{\lambda_{\text{rest}}}$$
- So small redshifts are usually converted to recession velocities using the following formula:
  $$v_r = z \times c \ (\text{when} \ z \ll 1)$$
- This relation breaks at $z > 1$, when it implies galaxies are moving away from us at speeds greater than that of light. Cosmological redshifts are not due to Doppler effects, but due to the increase in scale.
A RELATION BETWEEN DISTANCE AND RADIAL VELOCITY AMONG EXTRA-GALACTIC NEBULAE

BY EDWIN HUBBLE

MOUNT WILSON OBSERVATORY, CARNEGIE INSTITUTION OF WASHINGTON

Communicated January 17, 1929

Determinations of the motion of the sun with respect to the extra-galactic nebulae have involved a $K$ term of several hundred kilometers which appears to be variable. Explanations of this paradox have been sought in a correlation between apparent radial velocities and distances, but so far the results have not been convincing. The present paper is a re-examination of the question, based on only those nebular distances which are believed to be fairly reliable.

Distances of extra-galactic nebulae depend ultimately upon the application of absolute-luminosity criteria to involved stars whose types can be recognized. These include, among others, Cepheid variables, novae, and blue stars involved in emission nebulosity. Numerical values depend upon the zero point of the period-luminosity relation among Cepheids, the other criteria merely check the order of the distances. This method is restricted to the few nebulae which are well resolved by existing instruments. A study of these nebulae, together with those in which any stars at all can be recognized, indicates the probability of an approximately uniform upper limit to the absolute luminosity of stars, in the late-type spirals and irregular nebulae at least, of the order of $M$ (photographic) = $-6.3$. The apparent luminosities of the brightest stars in such nebulae are thus criteria which, although rough and to be applied with caution,
Hubble’s Law, also discovered in 1929

The slope of the velocity-distance relation measures the expansion rate of the universe, and it’s called the Hubble constant $H_0$. Initially, Hubble measured a value that is 10x too high at 500 km/s/Mpc.

Hubble (1929): “A Relation between Distance and Radial Velocity among Extra-Galactic Nebulae”
What are the implications of Hubble’s Law?

- *Not only* most galaxies are redshifted, *but also* their redshifts increase *linearly* with distance! $cz = H_0 D$

- Hubble’s Law indicates (1) the universe is expanding uniformly everywhere and (2) the universe had a beginning.
Hubble Flow: Visualizing Expansion in 1D

• Simple expansion model: paper clips on a rubber band
• As the rubber band stretches, an ant riding on clip B:
  • observes itself as stationary
  • observes clip F moving away twice as fast as clip D
  • observes clip A and C moving away at the same speed
• An ant on any paper clip would make similar observations.
Hubble Flow: Visualizing Expansion in 3D

- Galaxies as tracers of space shows that universe is expanding.
- Galaxies are moving away from us because space is created.
- New space is created uniformly in the Universe, leading to the linear proportionality between redshift and distance.

Similarly, galaxies do not move apart through space. Rather, galaxies get farther apart as space expands.
Hubble Flow: no “center” of the expansion, and non-Doppler redshifts

• It might appear that we are in the center of the universe, with all galaxies moving away. *But* there is no center: from any point in the universe, it would look the same.

• So the redshifts of galaxies are **not due to motion** (Doppler shift), but **due to space creation** (increasing in scale)

---

Coins on a rubber sheet

As a rubber sheet stretches, coins get farther apart, even though they are not moving across the sheet.
Cosmological redshift is NOT Doppler shift, it is caused by an increasing scale factor
Redshift and the Expansion

• Redshifts of galaxies are **not** due to Doppler shifts (relative motions)
• Instead, the light is “stretched out” as it travels through the expanding universe: this is known as **cosmological redshift**.
• The wavelength of light is getting longer over time because the scale factor is increasing.
• A higher redshift indicates a smaller scale factor. Light emitted at high redshift will be very stretched out.
An uniform expansion of the Universe must be scalable

- Imagine space like a rubber sheet, stretching the sheet increases the scale factor everywhere on the sheet, causing distances between grid points to increase.

**Visual Analogy**

- The stretching of a rubber sheet, or the expansion of space, is measured by the changing of the scale factor, $R_U$.
- If the distance between two points doubles, the scale factor $R_U$ doubles as well.
Cosmological redshift of photons emitted from a distant galaxy is caused by the increasing scale factor of the universe ($R_u$):

$$
\frac{R_U(z)}{R_U(0)} = R_U(z) = \frac{1}{1 + z} = \frac{\lambda_{\text{rest}}}{\lambda_{\text{observed}}} = \frac{\lambda(z)}{\lambda(0)}
$$
The Scale Factor

• The **scale factor** \( (R_U) \) is a measure of how much the universe has expanded.

• The scale factor gets smaller as we look back in time.
  • For example, when \( R_U = 0.5 \), the universe was half of its current size.

• The expansion pulls galaxies apart but does not destroy galaxies (yet!):
  • At scales smaller than the Local Group, gravitational forces can overcome the space expansion.
Redshift gives the scale factor of the Universe at the emitted time

- The redshift tells us how much the universe has expanded since a galaxy’s light was emitted.
- Write $R_U$ as the scale factor, then

\[
R_U = \frac{1}{1 + z} = \frac{\lambda_{\text{rest}}}{\lambda_{\text{observed}}}
\]

- Example: $z = 0$ means today, when $R_U = 1.0$. This is the maximum scale factor.
- Example: $z = 1$ means $R_U = 0.5$. The universe was half its current size when light was emitted from this galaxy.
- Example: $z = 9$ means $R_U = 0.1$
What is redshift? Classical vs. Relativistic Doppler Shift, and Scale Factors

- The **classical Doppler shift formula**,
  \[ 1 + z = \frac{\lambda_{\text{obs}}}{\lambda_0} = 1 + \frac{v_r}{c} \]
gives recession velocity:
  \[ v_r = cz \]
- The **relativistic Doppler shift formula**, 
  \[ 1 + z = \frac{\lambda_{\text{obs}}}{\lambda_0} = \sqrt{1 + \frac{v_r}{c}} \frac{1}{1 - \frac{v_r}{c}} \]
gives recession velocity:
  \[ v_r = c \frac{(1 + z)^2 - 1}{(1 + z)^2 + 1} \]
- But, **cosmological redshift** should be understood as a ratio of **scale factors**:
  \[ 1 + z = \frac{\lambda_{\text{obs}}}{\lambda_0} = \frac{1}{R_U(z)} \]
The Hubble Time \( t_H = 1/H_0 \)

An estimate of the age of the Universe
Expansion of space means that Universe was very small in distant past.

- If galaxies are getting farther apart now, they must be closer together in the past. Hubble’s law implies that the entire Universe started from a single point. Can we estimate when the Universe was a single point?
Visual Summary

• Because Hubble’s law is a linear relation, it does not matter which two galaxies you use to make this measurement; the end result will be the same.
The Hubble Time: How long ago did the Universe start expanding?

- **Assume space creation rate** is constant: \( \frac{dD}{dt} = \text{constant} = H(t)D(t) = H_0 D(t_0) \)
- Then, move \( dt \) to the right side and integrate both side from \( t=0 \) to \( t=t_0 \), we have:
  \[
  D(t_0) - D(t = 0) = H_0 D(t_0) \cdot (t_0 - 0)
  \]
- Given that \( D(t=0) = 0 \), we can solve the age of the Universe \( t_0 \) today:
  \[
  t_0 = \frac{1}{H_0} = \frac{1}{(70 \text{ km/s/Mpc})} \approx 14 \text{ Gyr}
  \]
Cosmological Redshifts measure the Scale Factor of the Universe

- **cosmological redshift** should be understood as a ratio of **scale factors**:

\[
1 + z = \frac{\lambda_{\text{obs}}}{\lambda_0} = \frac{1}{R_U(z)}
\]
Alternative derivation of the Hubble time using Scale Factor

- **Hubble’s law**: \( cz = H_0 D = H_0 [c (t_0-t)] \), where we used the *lookback time* times \( c \) to replace distance \( D \). Canceling \( c \) on both sizes, we have \( z = H_0 (t_0-t) \)
- **Scale factor**: \( R_u = 1/(1+z) \approx 1-z \) for \( z \ll 1 \)
- which give the *most recent expansion history* of the Universe: \( R_u = 1-H_0 (t_0-t) \)
- Extrapolating the relation to \( R_u(t=0) = 0 \), we solve for *Hubble time*: \( t_0 = 1/H_0 \)

Galaxies at low redshift \( (z < 0.1) \) give us a measurement of the slope of the expansion history: \( H_0 \)
The various possible expansion histories of the Universe

The Hubble time (\( t_0 = 1/H_0 \)) provides only an estimate of the Universe’s age.
A Changing Hubble Parameter $H(z)$

- The **Hubble constant**, $H_0 = cz/D$, **is the expansion rate of the Universe today.** In this definition, the expansion rate of the Universe is expected to change over time because the universe obviously was younger in the past.
- For the expansion rate at any time, we thus define $H(t) = \dot{R}_U(t)/R_U(t)$ as the **Hubble parameter**.
- At $t = t_0$ (today), this definition gives **Hubble’s Law**:
  \[
  \dot{R}_U(t_0) = H(t_0)R_U(t_0) \Rightarrow \dot{D} = H_0 D \text{ where } D = R_U D_{\text{comoving}}
  \]
Mathematical Description of the dynamics of the Universe:

The Friedmann Equation

Alexander Friedmann (1888 – 1925) was a Russian physicist and mathematician. Fought in WWI as an aviator. Died at age 37 from typhoid fever.
Fundamental Assumption: The Cosmological Principle

• Although galaxies tend to clump, on the largest cosmic scales, the Universe is both **homogeneous** and **isotropic**
  • **Homogeneous**: there is no preferred **location** in the Universe
  • **Isotropic**: there is no preferred **direction** in the Universe
Friedmann Equation: Classic Derivation based on Energy Conservation

- Imagine a **spherical shell** with **unit mass** in a **matter-only universe** with a **comoving radius** of $x$, as the universe expands:
  - its **physical radius** at time $t$ is $r(t) = R_U(t) \cdot x$,
  - its **expanding velocity** is $v(t) = \dot{R}_U(t) \cdot x$, and
  - the **mass enclosed** in the shell is
    \[ M(r) = \frac{4\pi}{3} [R_U(t)x]^3 \cdot \rho(t) \]
Friedmann Equation: Classic Derivation based on Energy Conservation

• Imagine a spherical shell with unit mass in a matter-only universe with a comoving radius of \( x \), as the universe expands:
  • its physical radius at time \( t \) is \( r(t) = R_U(t) \cdot x \),
  • its expanding velocity is \( v(t) = \dot{R}_U(t) \cdot x \), and
  • the mass enclosed in the shell is \( M(r) = \frac{4\pi}{3} [R_U(t)x]^3 \cdot \rho(t) \)

• We can write down the kinetic + gravitational potential energy for the unit-mass spherical shell:
  \[
  E = \frac{1}{2}v^2 - \frac{GM(r)}{r} = \frac{1}{2}\dot{R}_U(t)^2 x^2 - \frac{4\pi}{3}G\rho(t)R_U(t)^2 x^2
  \]

• This energy per unit mass must be the same for every shell with the same comoving radius \( x \), so we can define \( E \) with a \( k \) parameter:
  \[
  E \equiv -\frac{1}{2}kc^2 x^2
  \]

• Combining the two Eqs. and cancel out \( x^2 \) on both sides, we obtain:
  \[
  \left( \frac{\dot{R}_U^2}{R_U^2} - \frac{8}{3}\pi G\rho \right) R_U^2 = -kc^2
  \]
Recall the definition of the **Hubble parameter**:

\[ H(t) \equiv \frac{\dot{R}_U}{R_U} \]

- define a new parameter called **critical density**:

\[ \rho_c = \frac{3H^2}{8\pi G} \]

Note that because \( H \) varies, the critical density is not a constant.

- we can now rewrite the energy conservation

\[
\left( \frac{\ddot{R}_U}{R_U^2} - \frac{8}{3}\pi G\rho \right) R_U^2 = -kc^2
\]

as:

\[
H^2 \left( 1 - \frac{\rho}{\rho_c} \right) R_U^2 = -kc^2
\]

- next, define the density ratio as a dimensionless **density parameter** called Omega:

\[
\Omega_m \equiv \frac{\rho_m}{\rho_c}
\]

- Finally, we have the Friedmann equation in a **matter-only universe**:

\[
H^2 \left( 1 - \Omega_m \right) R_U^2 = -kc^2
\]
Calculating the Critical Density in Today’s Universe

• The critical density, $\rho_c$, varies as the universe evolves, just like the Hubble parameter. Its value Today, $\rho_c(t_0)$, can be calculated from the Hubble constant:

$$\rho_c = \frac{3H_0^2}{8\pi G}$$

• If we rewrite $H_0 = 70 \text{ km/s/Mpc}$ as $H_0 = 2.3 \times 10^{-18}/s$ by converting Mpc to km, then the critical density of Today’s universe is:

$$\rho_c = \frac{3 \times (2.3 \times 10^{-18}/s)^2}{8 \times \pi \times [6.67 \times 10^{-20}\text{km}^3/(\text{kg s}^2)]}$$

$$\rho_c = 9.5 \times 10^{-27}\text{kg/m}^3$$

• Given that $\rho = \mu m_H n$, this is equal to a hydrogen number density of **5.7 hydrogen atoms per cubic meter** ($m_H = 1.67\times10^{-27} \text{ kg}$).

• It seems small, but the observed mass density of **ordinary matter, averaged over large volumes**, is less than **one hydrogen atom per cubic meter** ($n < 1 \text{ m}^{-3} = 1e-6 \text{ cm}^{-3}$).
Expansion histories predicted by the Friedmann Equation

Part I: matter-only universe
Solving the Friedmann Equation in a Matter-Only Universe

• The **Friedmann Equation (FE)** in a **matter-only universe** is:

\[ H^2 (1 - \Omega_m) R_U^2 = -kc^2 \]

where the original terms were replaced by three key parameters:

• **Hubble parameter**: \( H(t) \equiv \frac{\dot{R}_U}{R_U} \),

• **critical density**: \( \rho_c = \frac{3H^2}{8\pi G} \), and

• **density parameter**: \( \Omega_m \equiv \frac{\rho_m}{\rho_c} \),

• To solve the Friedmann Equation, we need

  • the **boundary condition** at \( t = t_0 \):

    \[ H = H_0, \ R_U = 1, \ \text{thus} \ H_0^2(1 - \Omega_{m,0}) = -kc^2 \]

  • the **density relation** for matter:

    \[ \frac{\Omega_m}{\Omega_{m,0}} = \frac{\rho_m \rho_{c,0}}{\rho_{m,0} \rho_c} = \frac{\rho_m}{\rho_{m,0}} \frac{H_0^2}{H^2} \]

• Replacing \(-kc^2\) and \(\Omega_m\) with the above two relations, we arrive at a solution of the **Hubble parameter** as a function of **redshift** or scale factor:

\[ H^2 = \frac{H_0^2}{R_U^2} \left[ (1 - \Omega_{m,0}) + \Omega_{m,0}/R_U \right] \]
Solutions of the Friedmann Equation: $H$ vs. $z$ and $t$ vs. $z$

• Plug in the boundary condition and the density parameter relation:

\[ H^2 = \frac{H_0^2}{R_U^2} [(1 - \Omega_{m,0}) + \frac{\Omega_{m,0}}{R_U}] \]

• The above is the solution for the Hubble parameter. For example, for \( \Omega_{m,0} = 1 \) \( \Rightarrow H = \frac{H_0}{R_U^{3/2}} = H_0(1 + z)^{3/2} \)

• To solve for the time evolution, we need to express \( H(t) \equiv \frac{\dot{R}_U}{R_U} \):

\[ \left( \frac{1}{R_U} \frac{dR_U}{dt} \right)^2 = \frac{H_0^2}{R_U^2} [(1 - \Omega_{m,0}) + \frac{\Omega_{m,0}}{R_U}] \]

• For simplicity, we assume \( \Omega_{m,0} = 1 \) (a universe where density equals critical density). Separate time $t$ and scale factor $R_U$ to two sides:

\[ dt = \frac{\sqrt{R_U} dR_U}{H_0} \]

• Then integrate the differential equation from $R_U = 0$ (i.e., $t = 0$) to $R_U = 1/(1+z)$ [i.e., $t(z)$], we can solve for time as a function of scale factor or redshift:

\[ t = \frac{2}{3H_0} R_U^{3/2} \text{ or } t(z) = \frac{2}{3} t_H (1 + z)^{-3/2} \text{ or } R_U = (3H_0 t/2)^{2/3} \]
Predicted Expansion History if Only Matter Is Involved

The expansion history depends on $\Omega_{m,0}$, while $H_0$ sets the overall scale.

- $\Omega_{m,0} < 1$: sub-critical, expanding forever.
- $\Omega_{m,0} = 1$: critical, expanding forever, but expansion rate approaches zero as time goes. This critical universe is called Einstein-de Sitter universe.
- $\Omega_{m,0} > 1$: super-critical expansion stops and the universe collapses. (Big Crunch)
The Total Normal Matter Density is Sub-Critical

- Ordinary matter in galaxies, IGM, and ICM: $\Omega_{m,0} = 4.5\%$ (today).
- Dark matter increases $\Omega_{m,0}$ to 32\% (today).
Space-Time Geometry of the Universe

the *Robertson-Walker Metric*
In General Relativity, a **metric** is a function which measures *differential space-time distance* between two events and is **Lorentzian invariant**. The **Robertson-Walker metric** is the metric that describes the geometry of a **homogeneous, isotropic, expanding** universe. The metric in spherical coordinate system is:

\[
(ds)^2 = (c \cdot dt)^2 - R_U(t)^2 \left[ \left( \frac{dx}{\sqrt{1 - kx^2}} \right)^2 + (xd\theta)^2 + (x \sin \theta d\phi)^2 \right]
\]

where \(R_U\) is the scale factor, \(x\) is the **comoving** radial distance \(x \equiv r(t)/R_U(t)\), \(k\) is the **comoving** curvature \(k \equiv K(t)R_U(t)^2\). The same terms are in Friedmann Equation.

Photons travel along **null geodesics** \((ds = 0, \text{ i.e., proper time is frozen})\). Along the **radial direction** \((d\theta = d\phi = 0)\), we have:

\[
\frac{dx}{\sqrt{1 - kx^2}} = \frac{c}{R_U(t)} dt
\]

Follow the path of two adjacently emitted photons (separated by one wavelength:
\(\delta t = \lambda_e/c, \delta t_o = \lambda_o/c, \ 1 + z = \lambda / \lambda_e \)) by integrating from **emitter** to **observer**:

\[
\int_{x_e}^{x_o} \frac{dx}{\sqrt{1 - kx^2}} = \int_{t_e}^{t_o} \frac{cdt}{R_U(t)} = \int_{t_e+\delta t_e}^{t_o+\delta t_o} \frac{cdt}{R_U(t)} = \int_{t_e}^{t_o} \frac{cdt}{R_U(t)} + \int_{t_o+\delta t_o}^{t_e+\delta t_e} \frac{cdt}{R_U(t)} - \int_{t_e}^{t_e+\delta t_e} \frac{cdt}{R_U(t)}
\]

which gives us the **redshift—scale-factor relation**

\[
\frac{c\delta t_o}{R_U(t_o)} = \frac{c\delta t_e}{R_U(t_e)} \Rightarrow R_U(t_e) = \frac{\delta t_e}{\lambda_e} = \frac{1}{1 + z}
\]
The curvature parameter $k$ in the Friedmann Equation

- The universe has three possible geometry types determined by $\Omega_0$ & $H_0$, given the boundary condition today $k = -\frac{H_0^2(1 - \Omega_0)}{c^2}$ (Unit of $k$: 1/Mpc$^2$)

  - $k = 0$ ($\Omega_0 = 1$): Flat universe, infinite.
  - $k < 0$ ($\Omega_0 < 1$): Open universe, infinite, like the surface of a saddle.
  - $k > 0$ ($\Omega_0 > 1$): Closed universe, finite, like the surface of a sphere.

2D Analogies

- **a.** Flat geometry
  - If $\Omega_m + \Omega_\Lambda = 1$, the universe is flat.
  - Sum of angles = 180°
  - Circumference = $2\pi r$

- **b.** Open (saddle) geometry
  - If $\Omega_m + \Omega_\Lambda < 1$, the universe is open.
  - Sum of angles < 180°
  - Circumference < $2\pi r$

- **c.** Closed (spherical) geometry
  - If $\Omega_m + \Omega_\Lambda > 1$, the universe is closed.
  - Sum of angles > 180°
  - Circumference < $2\pi r$
Expansion histories predicted by the Friedmann Equation

Part II: matter + radiation + dark energy universe
By defining a new parameter called critical density: \( \rho_c = \frac{3H^2}{8\pi G} \), we have derived the Friedmann Equation for matter-only universe:

\[
H^2 \left(1 - \frac{\rho}{\rho_c}\right) R^2_U = -kc^2
\]

The full General Relativity version of the Friedmann Equation is:

\[
H^2 \left[1 - \left(\frac{\rho_m}{\rho_c} + \frac{\rho_\gamma}{\rho_c} + \frac{\Lambda c^2}{8\pi G \rho_c}\right)\right] R^2_U = -kc^2
\]

There are now three density ratios, i.e., define three Omega’s:

- \( \Omega_m \equiv \frac{\rho_m}{\rho_c} \), ordinary matter (baryons and dark matter)
- \( \Omega_\gamma \equiv \frac{\rho_\gamma}{\rho_c} \), relativistic matter (light and neutrinos)
- \( \Omega_\Lambda \equiv \frac{\Lambda c^2}{8\pi G \rho_c} \), dark energy (\( \Lambda \) is the cosmological constant and has the same physical unit as the curvature constant \( k \))

Replacing those, we have the final Friedmann Equation:

\[
H^2 \left[1 - (\Omega_m + \Omega_\gamma + \Omega_\Lambda)\right] R^2_U = -kc^2
\]
How to Solve the Complete Friedmann Equation? H(z) solution

• Boundary Condition at \( t = t_0 \):
  \[ H = H_0, \ R_U = 1, \ \text{thus} \ H_0^2(1 - \Omega_0) = -kc^2 \]

• Relations between density parameters and scale factor:
  \[
  \frac{\Omega_m}{\Omega_{m,0}} = \frac{\rho_m \rho_{c,0}}{\rho_{m,0} \rho_c} = \frac{\rho_m}{\rho_{m,0}} \frac{H_0^2}{H^2} = \frac{1}{R_U^3} \frac{H_0^2}{H^2}
  \]
  \[
  \frac{\Omega_\gamma}{\Omega_{\gamma,0}} = \frac{1}{R_U^4} \frac{H_0^2}{H^2} \quad \text{and} \quad \frac{\Omega_\Lambda}{\Omega_{\Lambda,0}} = \frac{H_0^2}{H^2}
  \]

• Write down the Friedmann Equation with the boundary condition:
  \[ H^2 \left[ 1 - (\Omega_m + \Omega_\gamma + \Omega_\Lambda) \right] R_U^2 = -kc^2 = H_0^2(1 - \Omega_0) \]
  then plug in the density parameter relations and rearrange:
  \[ H^2 = \frac{H_0^2}{R_U^2} \left[ (1 - \Omega_0) + \Omega_{m,0}/R_U + \Omega_{\gamma,0}/R_U^2 + \Omega_{\Lambda,0} R_U^2 \right] \]

• Examples:
  • For an empty universe:
    \[ \Omega_0 = \Omega_{m,0} = \Omega_{\gamma,0} = \Omega_{\Lambda,0} = 0 \Rightarrow H = H_0/R_U = H_0(1 + z) \]
  • For a matter-only flat universe (Einstein-de Sitter universe):
    \[ \Omega_0 = \Omega_{m,0} = 1, \Omega_{\gamma,0} = \Omega_{\Lambda,0} = 0 \Rightarrow H = H_0/R_U^{3/2} = H_0(1 + z)^{3/2} \]
How to Solve the Complete Friedmann Equation? t(z) or R_u(t) solution

- Write down the Friedmann Equation with the boundary condition and replace Hubble parameter with scale factor, \( H(t) \equiv \frac{\dot{R}_U}{R_U} \), we have
  \[
  \left( \frac{1}{R_U} \frac{dR_U}{dt} \right)^2 = \frac{H_0^2}{R_U^2} \left[ (1 - \Omega_0) + \Omega_{m,0}/R_U + \Omega_{\gamma,0}/R_U^2 + \Omega_{\Lambda,0}R_U^2 \right]
  \]
- For simplicity, assume a flat universe: \( \Omega_0 = \Omega_{m,0} + \Omega_{\gamma,0} + \Omega_{\Lambda,0} = 1 \).
- Separate time and scale factor into two sides of the equation:
  \[
  dt = \frac{1}{H_0} \frac{R_UdR_U}{\sqrt{\Omega_{m,0}R_U + \Omega_{\gamma,0} + \Omega_{\Lambda,0}R_U^4}}
  \]
- Integrating it from \( R_U=0 \) (i.e., \( t=0 \)) to \( R_U = 1/(1+z) \) [i.e., \( t(z) \)], we can solve for the \( t(z) \) relation for any given values of the density parameters.
- For example, for a matter-only critical/flat universe (a.k.a. the Einstein-de Sitter universe), we have solved for both \( H(z) \) and \( t(z) \):
  \[
  \Omega_0 = \Omega_{m,0} = 1, \quad \Omega_{\gamma,0} = \Omega_{\Lambda,0} = 0
  \]
  \[
  \Rightarrow H = H_0/R_U^{3/2} = H_0(1 + z)^{3/2}
  \]
  \[
  \Rightarrow t(z) = \frac{2}{3} t_H(1 + z)^{-3/2}
  \]
The cosmological constant $\Omega_\Lambda$ opposes gravity.

A nonzero $\Omega_\Lambda$ can cause a universe to expand faster and faster...

...and can even prevent the collapse of a universe with $\Omega_m > 1$.

Constraints on Cosmological Parameters: distance-redshift relation up to z ~ 1
Distance Modulus Measurements from Standard Candles

• Type Ia supernovae (SNe) have been used as standard candles to measure cosmological distances to other galaxies.
• They work as standard candles because presumably the white dwarfs have to reach 1.44 solar mass (the Chandrasekhar mass) to trigger the thermonuclear explosion.
• At its peak, the absolute magnitude in V-band (550 nm) is $M_V = -19$, and you measured a peak apparent magnitude of $m_V = 10$, what’s the distance in parsec?

\[
m - M = 5 \left[ \log d(\text{parsec}) - 1 \right]
\]

\[
d(\text{parsec}) = 10^{1 + 0.2(m - M)}
\]

\[
10 \text{ parsec} \times 10^{0.2(10 - (-19))} = 6.3 \text{ Mpc}
\]
Simple Distance Predictions from Hubble’s Law: $cz = H_0 D \rightarrow D = cz / H_0$, this approximation is valid at $0.02 < z < 0.2$ (why there is a lower limit?)

The straight line that best fits the data corresponds to $H_0 = 71$ km/s/Mpc.
Hubble Diagram: Distance Modulus vs. Cosmological Redshifts

Cosmological parameters can be constrained by comparing DM measurements (data points) with model predictions (curves) for a range of redshifts. For standard model, one uses these Eqs:

\[ D_L = (1 + z) \int_0^z \frac{cdz'}{H(z')} \]

\[ H^2 = \frac{H_0^2}{R_U^2} \left[ (1 - \Omega_0) + \Omega_{m,0}/R_U + \Omega_{\gamma,0}/R_U^2 + \Omega_{\Lambda,0}/R_U^2 \right] \]

\[ \mu = m - M = 5 \log D_L^{Mpc}(z; H_0, \Omega_M, \Omega_\Lambda) + 25 \]

The Density Parameters of the Universe Today

How do they evolve over time?
What’s the predicted future?
Density Parameters Today

Planck Collaboration (2013)

\[ \sum \Omega_{i,0} = 1.0 \]

Density Parameters Today

- **Dark Matter**: 27%
- **Gas**: 4%
- **Galaxies**: 0.5%
- **Neutrinos**: <0.5%

Critical density as a function of time. Value below is present value, based on present value of the Hubble parameter $H$.

\[ \rho_c(t) = \frac{3H^2(t)}{8\pi G} \]

\[ \rho_{c,0} = \frac{3H_0^2}{8\pi G} = 9.47 \times 10^{-27} \text{ kg/m}^3 \]
Density Parameters vs. Time

- Dark Matter-dominated in the first 10 Gyrs, then Dark Energy dominated.

- At 13.7 Gyr ago:
  - Neutrinos: 10%
  - Photons: 15%
  - Atoms: 12%
  - Dark Matter: 63%

- At 3.7 Gyr ago:
  - Neutrinos: 10%
  - Photons: 15%
  - Atoms: 12%
  - Dark Matter: 23%
  - Dark Energy: 72%

- Today:
  - Neutrinos: 10%
  - Photons: 15%
  - Atoms: 12%
  - Dark Matter: 23%
  - Dark Energy: 72%

- Today's matter and vacuum density parameters:
  - Dark Matter Dominated:
    - \( \Omega_M \) (Matter Density)
    - \( \Omega_\Lambda \) (Vacuum Density)

- At 13.7 Gyr:
  - \( \Omega_M = 1.0 \)
  - \( \Omega_\Lambda = 0.0 \)

- At 3.7 Gyr ago:
  - \( \Omega_M = 0.2 \)
  - \( \Omega_\Lambda = 0.8 \)

- Now:
  - \( \Omega_M = 0.02 \)
  - \( \Omega_\Lambda = 0.98 \)
Predicted Evolution of Density Parameters

- Dark Matter-dominated in the first 10 Gyrs, then Dark Energy dominated
The Struggle to Determine the Hubble Constant ($H_0$)

Why $H_0$ is so important? Because it determines not only the current expansion rate, but also the geometry of the Universe.
Hubble (1929)

Hubble initially got $H_0 = 500 \text{ km/s/Mpc}$, which led to a young universe: $1/H_0 = 2 \text{ Gyrs.}$

CURRENT PROBLEMS IN THE EXTRAGALACTIC DISTANCE SCALE

ALLAN SANDAGE
Mount Wilson and Palomar Observatories
Carnegie Institution of Washington, California Institute of Technology
Received February 3, 1958

ABSTRACT

In principle, a decision between the simplest cosmological models (exploding cases with $\Lambda = 0$, $k = +1$, 0, $-1$, or the steady-state case) is possible from the observed velocity-distance relation. Two numbers are needed. These are $H$ and the deceleration parameter, $\ddot{R}/R_0H^2$. This paper discusses the determination of $H$.

Problems connected with the use of cepheid variables as distance indicators are discussed. Because of a finite width of the instability region for cepheids in the color-magnitude (C-M) diagram, intrinsic scatter in the period-color and period-luminosity (P-L) relation is expected. The observed period-color relation at median light for field cepheids in our Galaxy shows that Eggen’s type C variables are oscillating in a higher mode than cepheids of Eggen type A, B. The data show $Q_{AB}/Q_C \approx 1.9$. If the region of instability for cepheids in the C-M diagram has a width of $\Delta(B-V) = 0.2$ mag, then the P-L relation is expected to have a scatter of 1.2 mag. The intrinsically bluest cepheids should be the brightest. Arp’s two-color data for cepheids in the SMC confirm these predictions.

The brightest stars are discussed as distance indicators for galaxies beyond the local group. It is probable that knots identified by Hubble as brightest stars in more distant resolved galaxies are really H II regions. From data in M100, the stars appear to be 1.8 mag, fainter than the knots. This correction, together with a correction of 2.3 mag, to Hubble’s moduli for galaxies in the local group, suggests a total correction of about 4.1 mag. to the 1936 scale of distances. This gives $H \approx 75$ km/sec 10^6 pc or $H^{-1} \approx 13 \times 10^9$ years, with a possible uncertainty of a factor of 2. The connection of this value of $H$ with the time scale of exploding cosmologies is briefly discussed.
Evidence for a Hot Beginning: Discovery of the Microwave Background
If the universe started from a Big Bang, the hot early universe should have generated a blackbody radiation field that is detectable everywhere.

- If all matter started in a small volume, conditions would be very hot. This hot, dense gas would have emitted blackbody radiation, which should be detectable even today (after the long expansion stretched these photons).

- In 1948, Alpher, Gamow, and Herman made a prediction: The Planck spectrum of the thermal emission should be everywhere and it would be uniformly redshifted by the expansion of the universe to a temperature of about 5–50 K, peaking at microwave wavelengths. Their prediction was ignored or mostly forgotten.

- Wien’s displacement law: $\lambda_{\text{peak}} = (2.9 \text{ mm K})/T$

- Cosmological redshift: $\lambda_{\text{obs}} = \lambda_{\text{emit}}(1 + z)$

- Combining the above two, we have the relation the blackbody temperature when emitted and the observed temperature:

$$T_{\text{obs}} = T_{\text{emit}} / (1 + z)$$

In other words, the observed temperature today is much lower than the original temperature due to cosmic expansion.
Measuring the Cosmic Microwave Background

• This predicted spectrum was accidentally discovered in 1963 by Arno Penzias and Robert Wilson. They measured microwave emission in all directions and the observed temperature of the emission was about 3 K.
• We call this predicted spectrum the cosmic microwave background (CMB).
• This was the first clear evidence of the Big Bang.
Temperature Map from Single-wavelength Intensity Measurement
The Planck Curve Predict *Intensity* as a function of *T* and *λ*

\[ B_\lambda(T) \equiv \frac{2hc^2}{\lambda^5} \frac{1}{e^{\frac{hc}{kT}} - 1} \]

- It is determined by *Temperature*, so blackbody emission is also called *thermal emission*.
- **When *T* increases:**
  1. **Peak** shifts to shorter wavelength - *Wien’s Displacement Law*
  2. **Surface Flux**, the total area under each Planck curve, increases rapidly - *Stefan-Boltzmann Law*
  3. **Surface brightness (intensity)** increases at all wavelengths - e.g., infrared thermometers
• The COBE satellite (launched in 1989) was the first instrument to provide very accurate measurements of the CMB spectrum. It determined the temperature of the CMB today is 2.73 K by fitting a beautiful Planck curve to the data.

![Planck curve and COBE measurements](image-url)
Problem is that the observed CMB temperature can’t tell the original temperature of the blackbody

- Wien’s displacement law: \( \lambda_{\text{peak}} = (2.9 \ \text{mm K})/T \)
- Cosmological redshift: \( \lambda_{\text{obs}} = \lambda_{\text{emit}}(1 + z) \)
- Combining the above two, we have the relation the blackbody temperature when emitted and the observed temperature:
  \[
  T_{\text{obs}} = \frac{T_{\text{emit}}}{1 + z}
  \]
  in other words, the observed temperature today is much lower than the original temperature due to cosmic expansion.

- The above equation cannot constrain the temperature when the cosmic radiation background first emerged. In fact, infinite number of \((T_{\text{emit}}, z)\) combinations could give us the same 3 K observed temperature, for examples:
  - \(T_{\text{emit}} = 10 \ \text{K}, \ z = 2.3\)
  - \(T_{\text{emit}} = 100 \ \text{K}, \ z = 32\)
  - \(T_{\text{emit}} = 1000 \ \text{K}, \ z = 330\)
- We call that the two parameters \((T_{\text{emit}}, z)\) are degenerate.
How do we know when the CMB first started to propagate in the universe?

The epoch of hydrogen recombination
How did the CMB emerge?
First, EM waves are trapped in an ionized universe

- When the universe was hot and the gas was ionized, photons were trapped with matter.
  - Free electrons interact strongly with photons (Thomson scattering).
  - We cannot observe anything during this era. It’s as if the universe is filled with a dense fog.

In the ionized early universe, light was trapped by free electrons. Radiation had a blackbody spectrum.

At that time, it was as though the universe was filled with a thick fog.
How did the CMB emerge?

Then, protons and electrons recombined to form hydrogen

- Eventually, the expansion causes the temperature to cool enough that **protons** and **electrons** could form **neutral H atoms**: this phase-transition of the Universe is called **the epoch of recombination (EoR)**.

- At that time, light was no longer blocked from its travel by free electrons.

- **EoR** marks the earliest point in the universe that we can observe.

At recombination, the universe became transparent, and the blackbody radiation traveled freely through the universe.

Recombination was like the fog suddenly clearing.
CMB Photons travel straight to us from the last scattering surface

- Analogous to the *last scattering surface* that marks the surface of the Solar photosphere
Recall this slide in Chap 2 - The Sun? Last Scattering Surface

• The Sun has no solid surface, but the apparent surface of the Sun is the surface at which light can directly escape into space.
• Let’s call this surface the **last scattering surface** (a concept also used in cosmology). Note that its depth depends on (1) the angle we look into the Sun and (2) the wavelength of the photons.
• The layers above this point are known as the **atmosphere**, which can be directly observed.
The EM radiation background emerges when recombination completed

- Before **recombination**, photons cannot travel far before it is scattered by e-; after **recombination**, photons can freely travel and eventually reach us.
- Given the baryon density of the Universe, it can be shown that **Hydrogen recombination** completed when the universe was \( \sim 3000 \text{ K} \). This is the original temperature of the cosmic EM radiation field.
- Since we have proven \( T_{\text{observed}} = T_{\text{emitted}}/(1+z) \), and we know the CMB has a temperature is 2.7 K today, the redshift at which the CMB emerged must be around 1100: \( 1+z = T_{\text{emitted}}/T_{\text{observed}} = 3000 \text{ K}/2.7 \text{ K} \sim 1100 \)
Recombination drastically reduced the Jeans mass for gravitational instability, allowing galaxies to form. What would happen next?

\[ M_J \propto a^3 \]

\[ M_J \propto T^{-3} \]

\[ T_{\text{rad}} = 2.7a^{-1} \text{ K} = 2.7(1 + z) \text{ K} \]
Reionization of the Universe by Galaxies
(but why the universe is still transparent?)
Big Bang - Particles created - Ionized universe (opaque) - Recombination ($z \sim 1100$) - Dark Ages - Reionization ($z \sim 20-7$)

The Tension between local and CMB measurements of $H_0$

The tension between 68 and 73 km/s/Mpc in $H_0$ could be reconciled by small systematic errors of 0.154 in magnitude or 0.0001 in redshift.

Freedman et al. (2019)
The Expanding Universe

• Observations (facts)
  • Hubble-Lemaître Law & the Hubble “constant”
  • The Cosmic Microwave Background (CMB)

• Interpretations (theories)
  • The cosmological principle
  • Robertson-Walker metric
  • Friedman equation

• Observations + Theory
  • Accelerating Expansion: Evidence of dark energy
  • The cosmic composition

• Predictions of the Big Bang theory: how everything began?
What is redshift? Classical vs. Relativistic Doppler Shift, and Scale Factors

• The **classical Doppler shift formula**,
  
  \[ 1 + z = \frac{\lambda_{\text{obs}}}{\lambda_0} = 1 + \frac{v_r}{c} \]
  
gives recession velocity:
  
  \[ v_r = cz \]

• The **relativistic Doppler shift formula**,
  
  \[ 1 + z = \frac{\lambda_{\text{obs}}}{\lambda_0} = \sqrt{\frac{1 + v_r/c}{1 - v_r/c}} \]
  
gives recession velocity:
  
  \[ v_r = c \frac{(1 + z)^2 - 1}{(1 + z)^2 + 1} \]

• But, **cosmological redshift** should be understood as a ratio of **scale factors**:
  
  \[ 1 + z = \frac{\lambda_{\text{obs}}}{\lambda_0} = \frac{1}{R_U(z)} \]
How to Solve the Friedmann Equation? $H(z)$ solution

• The full GR version of the Friedmann (1922) Equation is:

$$H^2 \left[ 1 - \left( \frac{\rho_m}{\rho_c} + \frac{\rho_\gamma}{\rho_c} + \frac{\Lambda c^2}{8\pi G \rho_c} \right) \right] R^2_U = -kc^2$$

where $\rho_c = \frac{3H^2}{8\pi G}$ is the critical density at redshift $z$ and $H \equiv \dot{R}_U/R_U$ the Hubble parameter at time $t$ or redshift $z$.

• Define $\Omega$'s as critical density ratios:
  
  • $\Omega_m \equiv \rho_m/\rho_c$, **ordinary matter** (baryons and dark matter)
  • $\Omega_\gamma \equiv \rho_\gamma/\rho_c$, **relativistic matter** (light and neutrinos)
  • $\Omega_\Lambda \equiv \Lambda c^2/(8\pi G \rho_c)$, **cosmological constant** (dark energy)

• Replacing those, we have the final Friedmann Equation:

$$H^2 \left[ 1 - (\Omega_m + \Omega_\gamma + \Omega_\Lambda) \right] R^2_U = -kc^2$$

• Apply the boundary condition today, the Hubble parameter is:

$$H^2 = \frac{H_0^2}{R_U^2} \left[ (1 - \Omega_0) + \Omega_{m,0}/R_U + \Omega_{\gamma,0}/R^2_U + \Omega_{\Lambda,0}R^2_U \right]$$
How to Solve the Friedmann Equation? t(z) or \( R_u(t) \) solution

• Write down the Friedmann Equation with the boundary condition and replace Hubble parameter with scale factor, \( H(t) \equiv \dot{R}_U/R_U \), we have

\[
\left( \frac{1}{R_U} \frac{dR_U}{dt} \right)^2 = \frac{H_0^2}{R_U^2} [(1 - \Omega_0) + \Omega_{m,0}/R_U + \Omega_{\gamma,0}/R_U^2 + \Omega_{\Lambda,0}R_U^2]
\]

• For simplicity, assume a flat universe: \( k = 0 \) and \( \Omega_0 = 1 \).

• Separate time and scale factor into two sides of the equation:

\[
dt = \frac{1}{H_0} \frac{R_U dR_U}{\sqrt{\Omega_{m,0} R_U + \Omega_{\gamma,0} + \Omega_{\Lambda,0}R_U^4}}
\]

• Integrating it from \( R_U=0 \) (i.e., \( t=0 \)) to \( R_U = 1/(1+z) \) [i.e., \( t(z) \)], we can solve for the \( t(z) \) relation for any given values of the density parameters.

• For example, for a matter-only flat universe (Einstein-de Sitter universe), we have solved for both \( H(z) \) and \( t(z) \):

\[
\Omega_0 = \Omega_{m,0} = 1, \Omega_{\gamma,0} = \Omega_{\Lambda,0} = 0
\]

\[
\Rightarrow H = H_0/R_U^{3/2} = H_0(1 + z)^{3/2}
\]

\[
\Rightarrow t(z) = \frac{2}{3} t_H (1 + z)^{-3/2}
\]
Temperature-Redshift Relation of the Cosmic Background Radiation

- Wien’s displacement law: $\lambda_{\text{peak}} = (2.9 \text{ mm K})/T$
- Cosmological redshift: $\lambda_{\text{obs}} = \lambda_{\text{emit}}(1 + z)$
- Combining the above two, we have the relation the blackbody temperature when emitted and the observed temperature:

$$T_{\text{obs}} = T_{\text{emit}} / (1 + z)$$

in other words, the observed temperature today is much lower than the original temperature due to cosmic expansion.

- The above equation cannot constrain the temperature when the cosmic radiation background first emerged. In fact, infinite number of $(T_{\text{emit}}, z)$ combinations could give us the same $3 \text{ K}$ observed temperature, for examples:
  - $T_{\text{emit}} = 10 \text{ K}, z = 2.3$
  - $T_{\text{emit}} = 100 \text{ K}, z = 32$
  - $T_{\text{emit}} = 1000 \text{ K}, z = 330$
  - We call that the two parameters $(T_{\text{emit}}, z)$ are degenerate.
