Gamma-Ray Bursts

• Detectors for 20 keV to 10 MeV
• Discovery
• The early years
• BATSE
• Fast versus slow bursts
• Uniformity and log $N$ – log $S$ relation
• BeppoSAX and discovery of afterglows
• Redshift measurements
• Connection of long GRBs to supernovae
Detectors for 20 keV – 10 MeV

• Can not use detectors for standard X-ray band (0.1-10 keV) because interaction cross-sections are too small – need more material.

• Thick semiconductor detectors
  – CdTe, CdZnTe, Ge, PbI$_2$, HgI$_2$, …
  – Work like X-ray semiconductor detectors
  – Typically have pixilated readout, one channel per pixel
  – Typical thickness 0.1 to several millimeters
Detectors for 20 keV – 10 MeV

- Scintillators – convert gamma-ray to optical photons then detect optical photons

Thick scintillators are cheaper than thick semiconductors.

Energy resolution is worse because only part of optical light is collected.

Photomultipliers are the traditional photo-detectors.
Photon produces an electron by interacting with photocathode.

Electron is accelerated by E-field, produces multiple electrons upon striking dynode. Several stages of dynodes can give multiplications of $10^6$. Response time is in nanoseconds.
Discovery

Vela 5 a/b (launched in 1969) and Vela 6 a/b were each pairs on opposite sides of a circular orbit 250,000 kilometers in diameter. Gamma-ray detector 60 cm\(^3\) of CsI. Events could be timed to an accuracy ~ 0.2 s, sometimes as good as 0.05 s.

The direction angle to the event with respect to the line between a pair of satellites could thus be determined to about 1/5th of a radian based on the difference in trigger times for the two satellites.

Discovery

1970 August 22 burst from Klebesadel et al. (1973).

Burst durations ranged from 0.1 s to 30 s.

Burst fluences ranged from $10^{-5} \text{ erg cm}^{-2}$ to $2 \times 10^{-3} \text{ erg cm}^{-2}$.

Peak of spectrum above 10 keV maybe up to 10 MeV.
Interpretation of Early Bursts

Main question was Galactic or extra-Galactic.

Galactic: distance $\sim 10$ kpc, total energy $\sim 10^{41} - 10^{43}$ erg

Extragalactic: distance $\sim 10$ Mpc, total energy $\sim 10^{47} - 10^{49}$ erg
BATSE

Large Area Detector - disk of NaI scintillation crystal 20 inches in diameter and 0.5 inch thick read out with three 5-inch PMTs. Quarter-inch plastic scintillation detector in front of the LAD for anticoincidence. Sensitive from 25 keV to 2 MeV.

Spectroscopy Detector - NaI(Tl) 5 inches in diameter and 3 inches thick. Single 5 inch PMT.
BATSE on CGRO

Eight LADs are oriented like the eight faces of an octahedron. Position of burst determined by relative counts in different detectors.
BATSE Bursts

BATSE operated for 9 years and detected 2704 bursts.

Huge variety of GRBs varying on time scales from $10^{-3}$ to $10^{3}$ seconds.

Bright bursts were localized to an accuracy of $2^\circ$ dim ones to $10^\circ$. This prevented identifying X-ray or optical counterparts.
Long vs Short GRBs

Characterize burst durations by $T_{50}$ and $T_{90}$. These are the minimum time intervals in which 50% or 90% of the burst fluence is contained.
Figure 9: The spectrum of GRB 910601 observed over a wide energy range, as measured by three experiments on CGRO (Share et al. 1994). A typical broad spectrum with a peak power at about 600 keV is seen. (The fitted spectral up-turn above 4 MeV is not significant.)
Long vs Short GRBs

HR32 is ratio of counts in 100-300 keV band versus counts in 50-100 keV band. Short bursts appear to be harder than long ones.
Isotropy

First 153 bursts: $<\cos \theta> = -0.002 \pm 0.006$, $<\sin^2 b> = 0.310 \pm 0.006$

For isotropic: $<\cos \theta> = 0.0$, $<\sin^2 b> = 0.333$
Flux distribution

$C_{\text{max}}$ is burst maximum count rate, $C_{\text{min}}$ is trigger threshold.

$V/V_{\text{max}} = (C_{\text{max}}/C_{\text{min}})^{-3/2}$

For homogeneous distribution, expect $\log(N>S)$ vs $\log(S)$ to follow $-3/2$ power law and $<V/V_{\text{max}}>$ = 0.5.

Find $<V/V_{\text{max}}>$ = 0.35±0.02 and deviations from -3/2 power law.

Conclude GRBs are isotropic, but not homogeneous.
BeppoSAX

Italian-Dutch X-ray astronomy satellite.

Launched 1996.

Carried several X-ray instruments.

For GRBs, the critical instrument turned out to be the Wide Field Cameras: Proportional counters with effective area of 140 cm$^2$ and a coded aperture mask covering 2-30 keV with a field of view 20° × 20°.
First BeppoSAX WFC Burst

WFC light curve (top), GRB monitor light curve (bottom), narrow field instrument image (right) from Costa et al. 1997.
First GRB Optical Counterpart

Found decaying optical source inside BeppoSAX NFI error circle.

Found to lie near a faint and distant galaxy.
GRB 970508 – Optical Counterpart

BeppoSAX X-ray localization enabled detection of an optical transient. It was then possible to obtain an optical spectrum.
GRB970508 – Absorption Lines: $z=0.835$

Metzger et al. 1997

Optical Emission

$F_\nu, 10^{-29}$ erg cm$^{-2}$ s$^{-1}$ Hz$^{-1}$

$\lambda$, Angstroms

Fe II, Fe II, Mg II, Mg II I
Host Galaxy Detected for GRB970508

Fig. 2.— The weighted average spectrum of the host galaxy of GRB 970508, obtained at the Keck telescope. The spectra were smoothed with a Gaussian with a $\sigma = 5\,\text{Å}$, roughly corresponding to the instrumental resolution. Prominent emission lines are labeled.
Redshifts either measured for host galaxy after burst, or from absorption lines in optical after glow of the burst itself.

Clearly most bursts are at cosmological distances.

In BeppoSAX era, all bursts with afterglows and optical counterparts were long bursts.

Host Galaxies

Hosts have high star formation rates and are generally similar to other star-forming galaxies at these redshifts.

Holland 2001
Location of GRB within Host

GRB 970228

GRB 970828

GRB 980703

GRB 990123

GRB 990510

GRB 990712
Location of GRB within Host

The environments of GRBs show higher gas densities, higher metallicities, and higher dust content than random locations in host galaxies.

Suggests that GRBs occur in star forming regions.
GRB Locations

- GRB hosts are star-forming galaxies
- GRBs trace the stellar distribution (in distance from galaxy center)
- GRBs occur in dense environments (probably star forming regions)

- Suggests long GRBs are associated with star formation and occur promptly after star formation
Connection of GRBs to Supernovae

SN 1998bw was found in the 8’ error circle of GRB 980425 in observations made 2.5 days after the burst.

A slowly decaying X-ray source was subsequently found in the same galaxy ($z = 0.0085$) and identified with the GRB.

However, the GRB was very underluminous and the SN was very usual with peculiar line emission (no H, no He, no Si at 615 nm).

Radio emission a few days after GRB indicated relativistic outflow with energy $\sim 3 \times 10^{50}$ erg.

Thought to be oddball GRB and SN.
GRB030329 and SN 2003dh

Clear spectroscopic signature of a SN, broad emission lines, found after decay of afterglow of GRB030329.

“Smoking gun” linking GRBs and SNe.
SN 2003dh versus SN 1998bw
SN Bumps

light curves of GRB 970228

**FIG. 3.**—The V-, Rc-, and Ic-band lightcurves of GRB 970228 (fluxes versus time). The dotted curves indicate power-law decays with $\alpha = -1.73$, and redshifted SN 1998bw light curves. The thick line is the resulting sum of SN and power-law decay light curves.
## GRB - Supernova

Only a tiny fraction of SN are observed to be GRBs
